Modernizing Maryland’s Grid with All-Electric Buildings

Maryland must modernize its electric grid to maintain reliable and affordable power. Efficient, all-electric buildings can be a valuable tool in optimizing this evolution. There’s no need to wait: today’s grid can already serve thousands of new electric systems as utilities continue long-term planning efforts.

Building the grid of the future starts today

Updating and expanding Maryland’s grid is essential to improving reliability and powering electrified buildings and vehicles as part of our clean energy transition. Managing this growth will require coordinated investments in grid infrastructure, distributed energy resources like solar and battery systems, and building technologies that give grid operators more flexibility. Utilities need to inform this process by creating infrastructure plans that reflect a climate-aligned trajectory.

U.S. electricity consumption will continue to rise with the growing adoption of all-electric vehicles and buildings

Grid-interactive technology could offset 20% of projected electric demand by 2030, helping manage grid growth.²

We are ready for accelerated heat pump adoption

Maryland policymakers and regulators should advance building electrification efforts to both catalyze and inform long-term grid planning. Today’s grid distribution system can already serve 3-5 times more heat pumps than are currently in operation.³ Utility operators are well-prepared to meet this growing demand as long-term plans are developed.

Today’s grid can support substantially more heat pumps³

- 20% of buildings currently use heat pumps⁴
- 67% could electrify with standard heat pumps
- 89% could electrify using high-performance heat pumps

² Future growth is expected to track past growth.

Electrification will change how our grid operates

Maryland’s infrastructure is designed to meet the maximum load (a.k.a. “peak demand”) that buildings require throughout the year. Today, peak demand is dominated by air conditioners running at full blast on the hottest day of summer. Replacing these units with more efficient heat pumps can reduce this summer peak and minimize the risk of summer blackouts.

Maryland will also see an increased winter peak as heating systems are electrified. In Maryland’s climate, this winter growth will result in a greater balance in seasonal grid usage, allowing utilities to serve more load with the same infrastructure and potentially reduce costs for consumers.

All-electric buildings can help modernize the grid

Maryland’s transition to a clean power grid will rely on several innovations in all-electric buildings to improve reliability while increasingly running on renewable energy. Together, the technologies described below can balance energy use throughout the day to reduce carbon emissions and electricity bills. They can also help prevent blackouts and allow for the continuation of essential services when the power does go out.

Efficient equipment
Heat pumps and other modern, energy efficient building systems reduce overall electricity consumption year-round.

Distributed energy resources
Solar, battery storage, and electric vehicles can act as grid assets and maintain building operations when the power goes out.

Grid interactive technology
Smart appliances and energy management systems let buildings shift power use during the day based on real-time grid conditions.

Microgrids
These networks cost-effectively balance operations across multiple buildings and support community-scale resilience.

Take action

Policymakers can help guide strategic investment in the grid in several ways:

- **Direct utilities to adopt ratemaking processes, tariffs, and incentives** to encourage the adoption of building energy management systems, on-site energy generation, and energy storage.
- **Improve state oversight** over transmission spending to prioritize regional and interregional projects that support grid decarbonization efforts.
